# Part 1: The method <table>.row-n(index) consumes the index of the row and produces the information about that row. Look at the dataset "US Jobs 2019." Choose 3 occupations and define them below.

# Example
comp-programmers = occupation-table.row-n(28)

# Occupation #1:
fundraiser = occupation-table.row-n(22)

# Occupation #2:
editor = occupation-table.row-n(54)

# Occupation #3:
pharmacist = occupation-table.row-n(56)

# Part 2: The method <table>.order-by("column", Boolean) consumes a column and a Boolean and produces a table sorted in ascending or descending order according to the Boolean. Define the table and sort the dataset according to the given column and conditions.

# Example: Define a table called "employed". Sort the table by total employed from greatest to least.

employed = occupation-table.order-by("tot-employment", false)

# Define a table called "med-wage". Sort the table by annual median wage from greatest to least.

med-wage = occupation-table.order-by("annual-median-wage", false)

#####################################
######################

# Part 3: Below is a list of functions. These functions will be used in Part 4.

fun is-high-med-wage(row): row["annual-median-wage"] >= 70000 end

fun is-higher-female-wage(row): row["female-weekly-median-wage"] >= row["weekly-median-wage"] end

# Define a function called "need-bachelors" that consumes a row and checks if the occupation in the row requires a Bachelor's degree.

fun needs-bachelors(row): row["educ-req"] == "Bachelor's degree" end

66
67  # Part 4: The method
    <table>.filter(function) consumes a
    function and produces a table that
    only shows rows where the function is
    true. Define the table and filter the
    dataset by the appropriate functions
    from Part 3.
68
69
70  # a. Define a table called "high-
    wage" that only shows occupations
    that have an annual median wage
    greater than $70000.
71
72  high-wage = occupation-
    table.filter(is-high-med-wage)
73
74  # b. Define a table called "higher-
    female" that only shows occupations
    that have a higher weekly median wage
    for women than the weekly median
    wage.
75
76  higher-female = occupation-
    table.filter(is-higher-female-wage)
77
78  # How many rows are in the "higher-
    female" table? What does this tell us
    about women's wages in the US?
79
80  # There are 10 rows. There are not
    many jobs where women make more money
    than men, though there are many jobs
    where men make more than women.
81
82
83  ######################################
    ######################
84
85  # Part 5: Samples of datasets can be
    used to make inferences about the
    whole dataset. The function "random-
    rows" takes in a table and a number
    of rows and creates a sample of
    random rows from the table.
86
87  # Define a table called "tiny-sample"
```
